String similarity

Q. How similar are two strings?

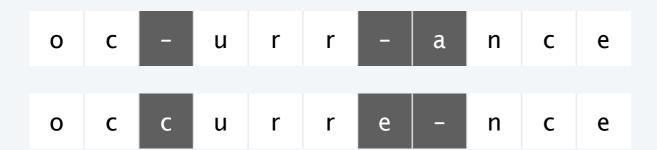

Ex. ocurrance and occurrence.

6 mismatches, 1 gap

1 mismatch, 1 gap

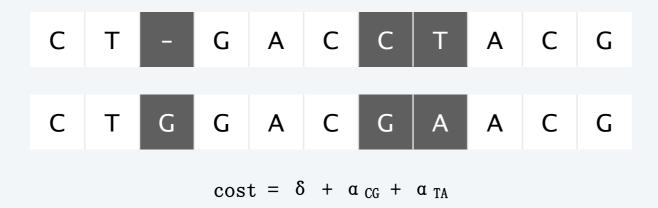

0 mismatches, 3 gaps

Edit distance

Edit distance. [Levenshtein 1966, Needleman-Wunsch 1970]

- Gap penalty δ ; mismatch penalty α_{pq} .
- Cost = sum of gap and mismatch penalties.

Applications. Unix diff, speech recognition, computational biology, ...

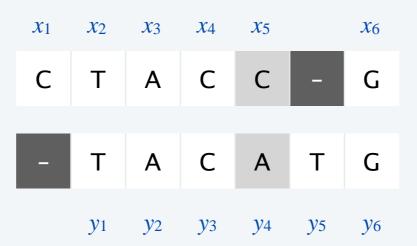

Goal. Given two strings $x_1 x_2 \dots x_m$ and $y_1 y_2 \dots y_n$ find min cost alignment.

Def. An alignment M is a set of ordered pairs $x_i - y_j$ such that each item occurs in at most one pair and no crossings.

 $x_i - y_j$ and $x_{i'} - y_{j'}$ cross if i < i', but j > j'

Def. The cost of an alignment *M* is:

$$cost(M) = \underbrace{\sum_{(x_i, y_j) \in M} \alpha_{x_i y_j}}_{\text{mismatch}} + \underbrace{\sum_{i: x_i \text{ unmatched}} \delta + \sum_{j: y_j \text{ unmatched}} \delta}_{\text{gap}}$$

an alignment of CTACCG and TACATG:

$$M = \{ x_2 - y_1, x_3 - y_2, x_4 - y_3, x_5 - y_4, x_6 - y_6 \}$$

Def. $OPT(i, j) = \min \text{ cost of aligning prefix strings } x_1 x_2 \dots x_i \text{ and } y_1 y_2 \dots y_j.$

Case 1. *OPT* matches $x_i - y_j$.

Pay mismatch for $x_i - y_j$ + min cost of aligning $x_1 x_2 ... x_{i-1}$ and $y_1 y_2 ... y_{j-1}$.

Case 2a. OPT leaves x_i unmatched. Pay gap for x_i + min cost of aligning $x_1 x_2 ... x_{i-1}$ and $y_1 y_2 ... y_j$.

Case 2b. *OPT* leaves y_j unmatched.

optimal substructure property (proof via exchange argument) Pay gap for y_i + min cost of aligning $x_1 x_2 ... x_i$ and $y_1 y_2 ... y_{j-1}$.

$$OPT(i, j) = \begin{cases} j\delta & \text{if } i = 0 \\ \alpha_{x_i y_j} + OPT(i-1, j-1) & \text{otherwise} \\ \delta + OPT(i, j-1) & \text{otherwise} \\ \delta + OPT(i, j-1) & \text{if } j = 0 \end{cases}$$

SEQUENCE-ALIGNMENT
$$(m, n, x_1, ..., x_m, y_1, ..., y_n, \delta, \alpha)$$

FOR $i = 0$ TO m
 $M[i, 0] \leftarrow i \delta$.

FOR $j = 0$ TO n
 $M[0, j] \leftarrow j \delta$.

FOR $i = 1$ TO m

FOR $j = 1$ TO n
 $M[i, j] \leftarrow \min \{ \alpha[x_i, y_j] + M[i-1, j-1], \delta + M[i-1, j], \delta + M[i, j-1] \}$.

RETURN M[m, n].

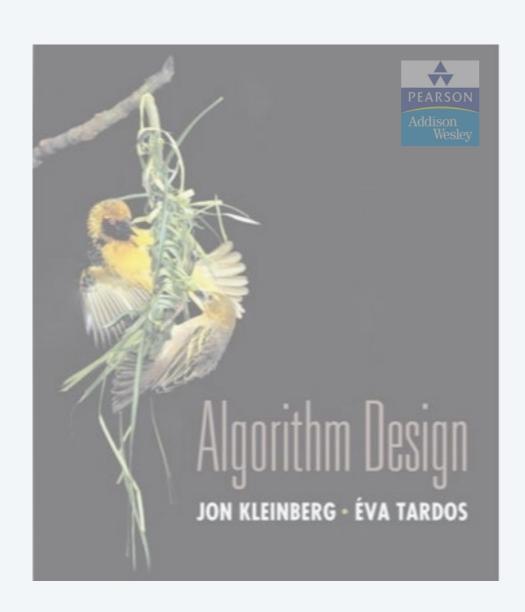

Theorem. The dynamic programming algorithm computes the edit distance (and optimal alignment) of two strings of length m and n in $\Theta(mn)$ time and $\Theta(mn)$ space.

Pf.

- Algorithm computes edit distance.
- Can trace back to extract optimal alignment itself.
- Q. Can we avoid using quadratic space?
- A. Easy to compute optimal value in O(mn) time and O(m+n) space.
 - Compute $OPT(i, \bullet)$ from $OPT(i-1, \bullet)$.

To fill entry in array, the

• But, no longer easy to recover optimal alignment itself. recurrence only needs information from the current column of array and the previous column of array

6. DYNAMIC PROGRAMMING II

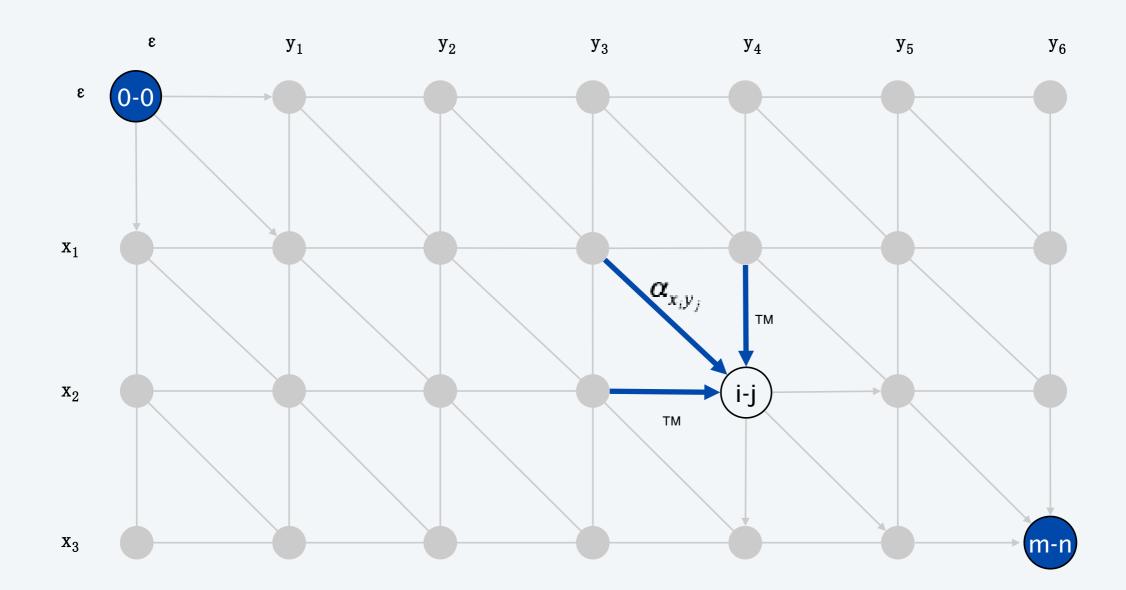

- sequence alignment
- Hirschberg's algorithm
- Bellman-Ford algorithm
- distance vector protocols
- negative cycles in a digraph

Theorem. There exist an algorithm to find an optimal alignment in O(mn) time and O(m+n) space.

- Clever combination of divide-and-conquer and dynamic programming.
- Inspired by idea of Savitch from complexity theory.

Programming G. Manacher Techniques Editor A Linear Space Algorithm for Computing Maximal Common Subsequences D.S. Hirschberg Princeton University The problem of finding a longest common subsequence of two strings has been solved in quadratic time and space. An algorithm is presented which will solve this problem in quadratic time and in linear space. Key Words and Phrases: subsequence, longest common subsequence, string correction, editing CR Categories: 3.63, 3.73, 3.79, 4.22, 5.25

- Let f(i, j) be shortest path from (0,0) to (i, j).
- Lemma: f(i,j) = OPT(i,j) for all i and j.

Hirschberg's algorithm

Edit distance graph.

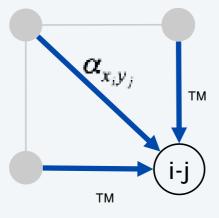

- Let f(i, j) be shortest path from (0,0) to (i, j).
- Lemma: f(i,j) = OPT(i,j) for all i and j.

Pf of Lemma. [by strong induction on i + j]

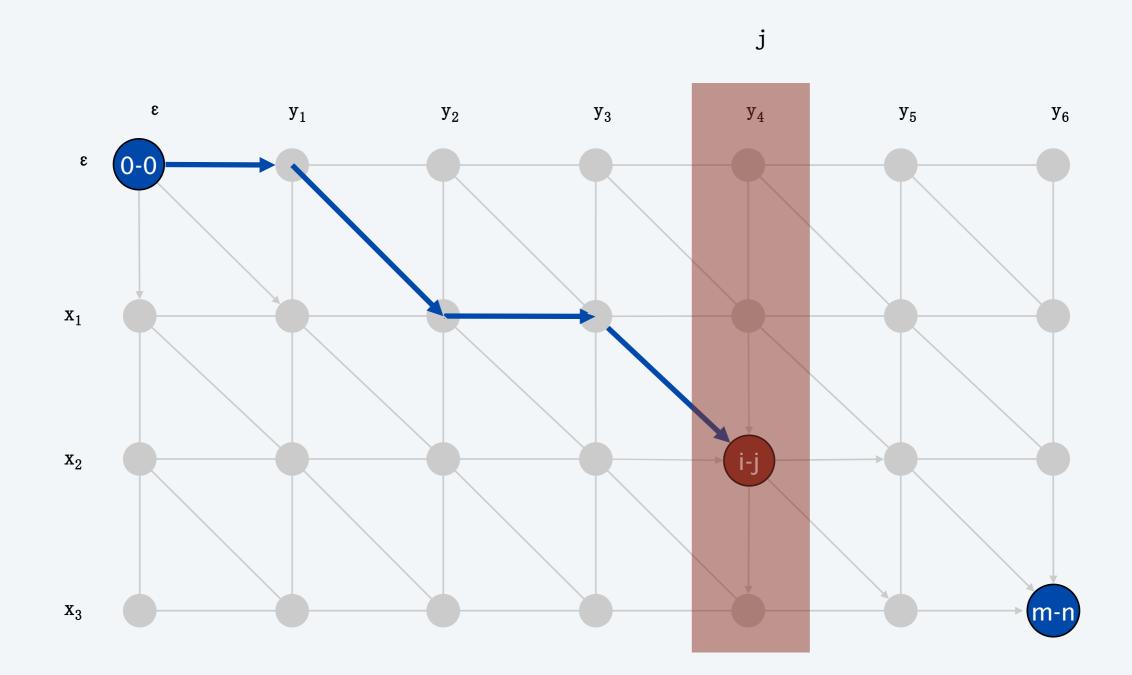

- Base case: f(0,0) = OPT(0,0) = 0.
- Inductive hypothesis: assume true for all (i', j') with i' + j' < i + j.
- Last edge on shortest path to (i, j) is from (i 1, j 1), (i 1, j), or (i, j 1).
- Thus,

$$\begin{array}{lcl} f(i,j) & = & \min\{\alpha_{x_iy_j} + f(i-1,j-1), \; \delta + f(i-1,j), \; \delta + f(i,j-1)\} \\ \\ & = & \min\{\alpha_{x_iy_j} + OPT(i-1,j-1), \; \delta + OPT(i-1,j), \; \delta + OPT(i,j-1)\} \end{array}$$

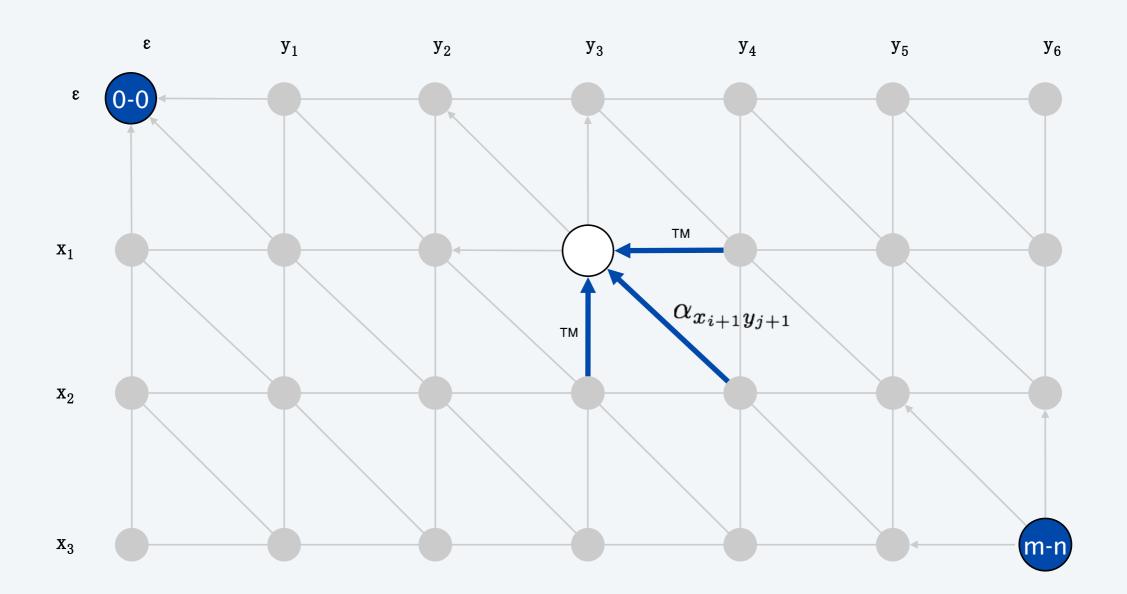

$$= OPT(i,j)$$

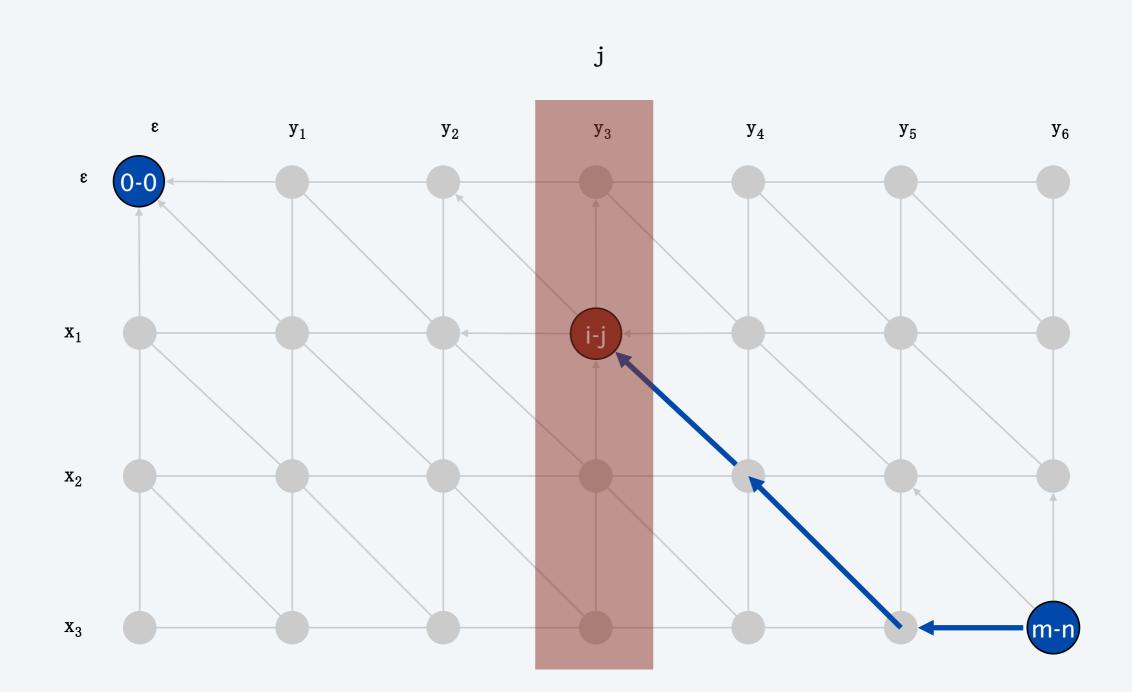

- Let f(i, j) be shortest path from (0,0) to (i, j).
- Lemma: f(i,j) = OPT(i,j) for all i and j.
- Can compute $f(\bullet, j)$ for any j in O(mn) time and O(m+n) space.

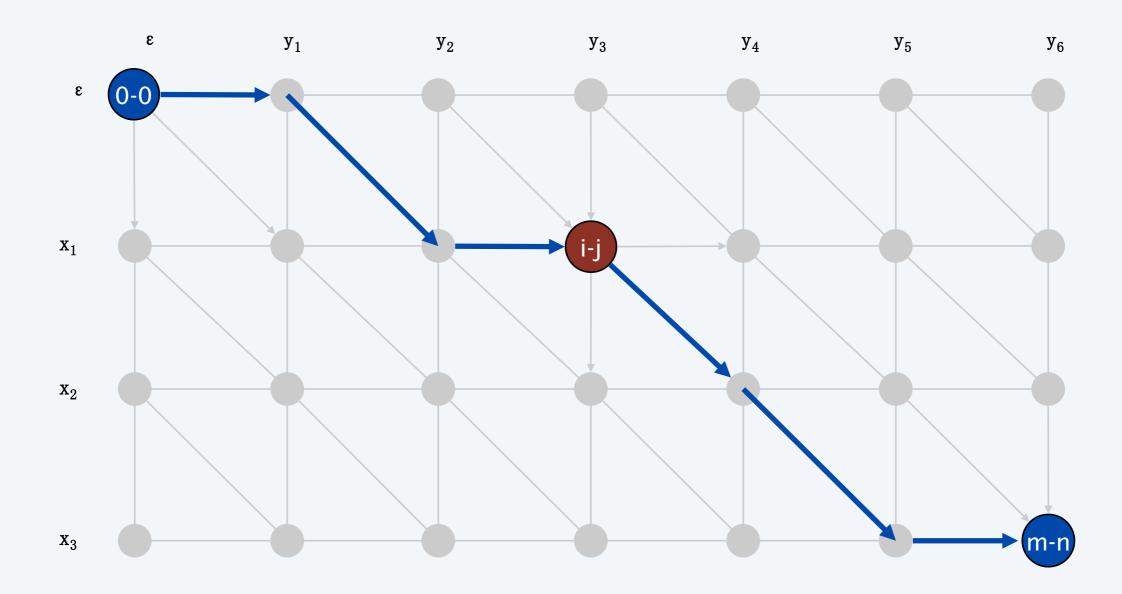

- Let g(i, j) be shortest path from (i, j) to (m, n).
- Can compute by reversing the edge orientations and inverting the roles of (0,0) and (m,n).

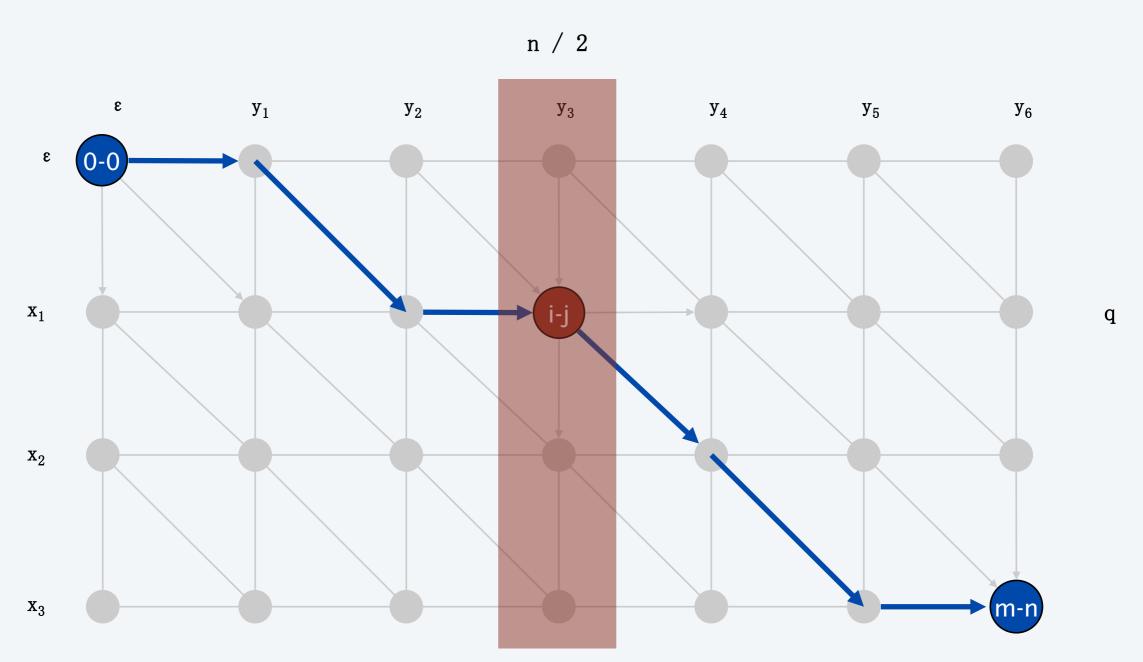

- Let g(i, j) be shortest path from (i, j) to (m, n).
- Can compute $g(\bullet, j)$ for any j in O(mn) time and O(m+n) space.

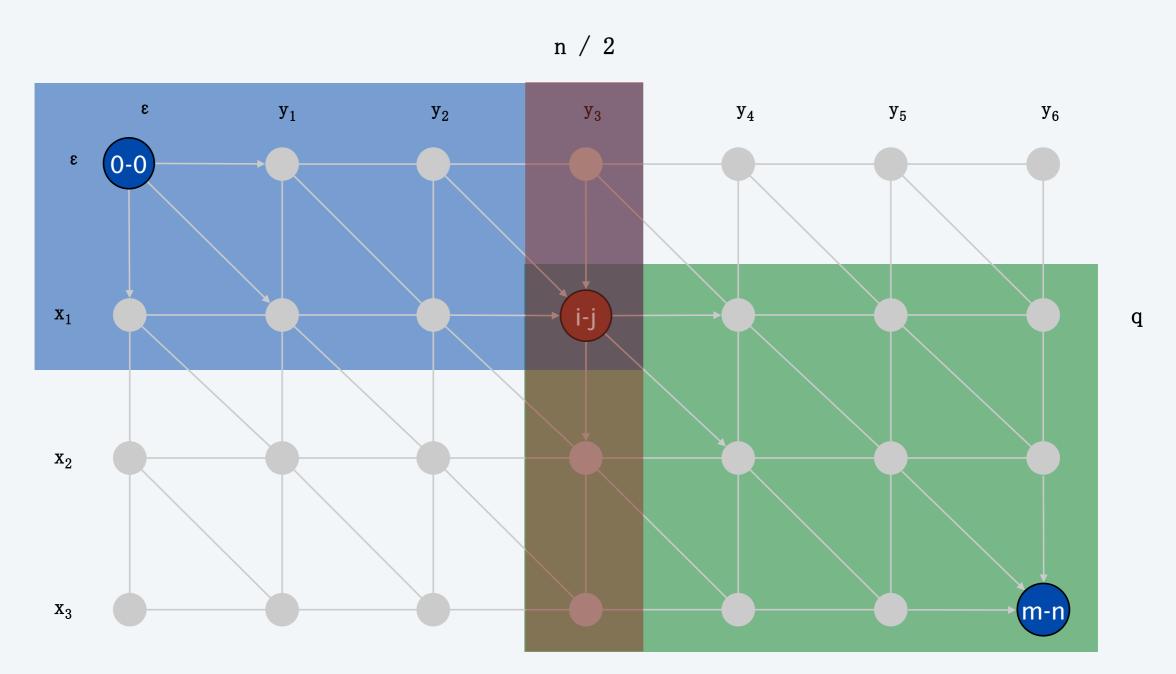

Observation 1. The cost of the shortest path that uses (i, j) is f(i, j) + g(i, j).

Observation 2. let q be an index that minimizes f(q, n/2) + g(q, n/2). Then, there exists a shortest path from (0, 0) to (m, n) uses (q, n/2).

Divide. Find index q that minimizes f(q, n/2) + g(q, n/2); align x_q and $y_{n/2}$. Conquer. Recursively compute optimal alignment in each piece.

Hirschberg's algorithm: running time analysis warmup

Theorem. Let $T(m, n) = \max$ running time of Hirschberg's algorithm on strings of length at most m and n. Then, $T(m, n) = O(m n \log n)$.

Pf.
$$T(m, n) \le 2 T(m, n/2) + O(m n)$$

 $\Rightarrow T(m, n) = O(m n \log n).$

Remark. Analysis is not tight because two subproblems are of size (q, n/2) and (m - q, n/2). In next slide, we save $\log n$ factor.

Hirschberg's algorithm: running time analysis

Theorem. Let $T(m, n) = \max$ running time of Hirschberg's algorithm on strings of length at most m and n. Then, T(m, n) = O(m n).

Pf. [by induction on *n*]

- O(mn) time to compute $f(\bullet, n/2)$ and $g(\bullet, n/2)$ and find index q.
- T(q, n/2) + T(m-q, n/2) time for two recursive calls.
- Choose constant c so that: $T(m, 2) \le c m$

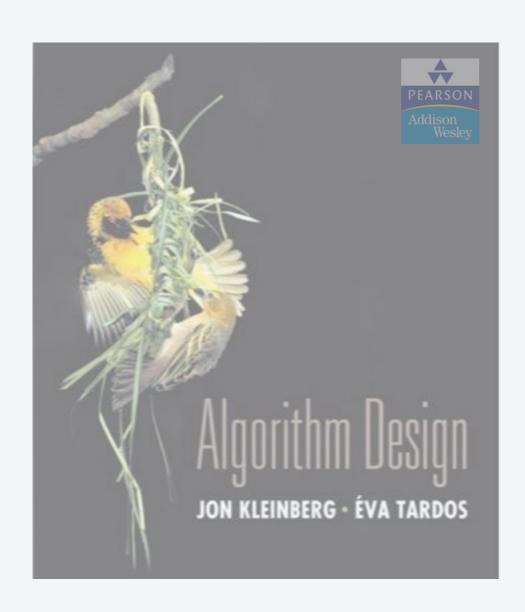

$$T(2, n) \leq c n$$

- Claim. $T(m, n) \leq 2cmn$.
- Base cases: m = 2 or n = 2.
- Inductive hypothesis: $T(m, n) \le 2cmn$ for all (m', n') with m' + n' < m + n.

$$T(m, n) \le T(q, n/2) + T(m - q, n/2) + cmn$$

 $\le 2cqn/2 + 2c(m - q)n/2 + cmn$
 $= cqn + cmn - cqn + cmn$
 $= 2cmn$

 $T(m, n) \le c m n + T(q, n/2) + T(m-q, n/2)$

6. DYNAMIC PROGRAMMING II

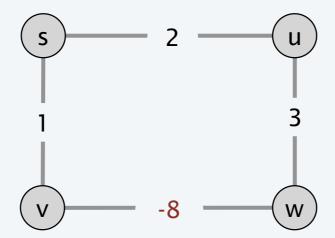

- sequence alignment
- Hirschberg's algorithm
- Bellman-Ford
- distance vector protocols
- negative cycles in a digraph

Shortest path problem. Given a digraph G = (V, E), with arbitrary edge weights or costs c_{vw} , find cheapest path from node s to node t.

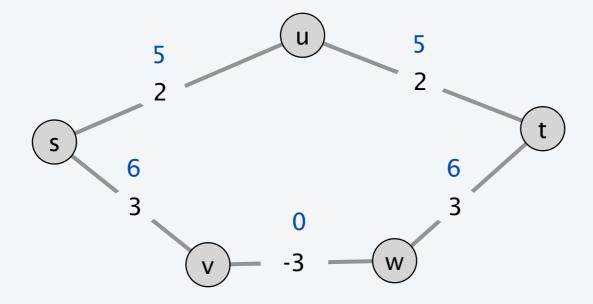

destination t

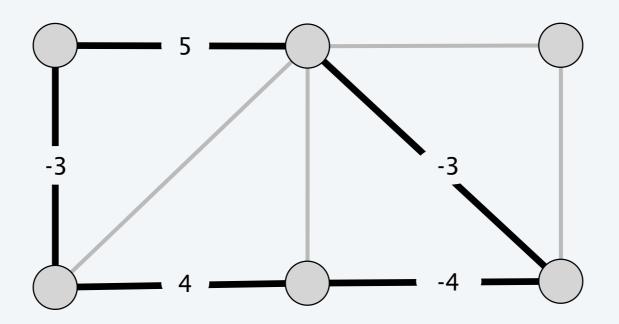

Dijkstra. Can fail if negative edge weights.

Reweighting. Adding a constant to every edge weight can fail.

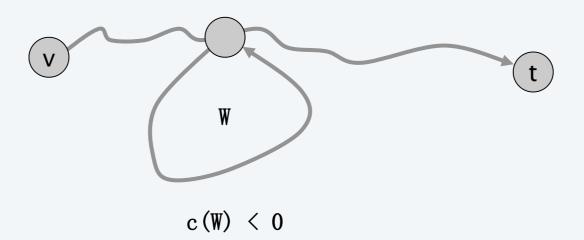

Def. A negative cycle is a directed cycle such that the sum of its edge weights is negative.

a negative cycle W :
$$c(W) = \sum_{e \in W} c_e < 0$$

Lemma 1. If some path from v to t contains a negative cycle, then there does not exist a cheapest path from v to t.

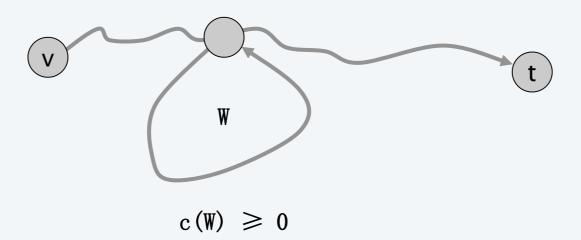

Pf. If there exists such a cycle W, then can build a $v \sim t$ path of arbitrarily negative weight by detouring around cycle as many times as desired. \blacksquare

Lemma 2. If G has no negative cycles, then there exists a cheapest path from v to t that is simple (and has $\leq n-1$ edges).

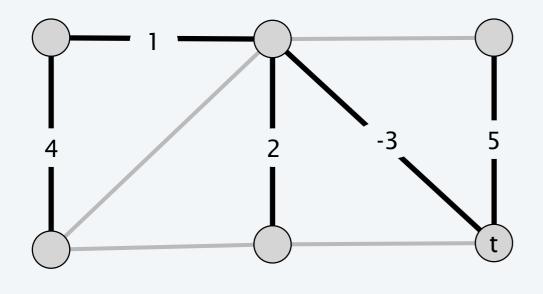

Pf.

- Consider a cheapest $v \sim t$ path P that uses the fewest number of edges.
- If P contains a cycle W, can remove portion of P corresponding to W
 without increasing the cost.

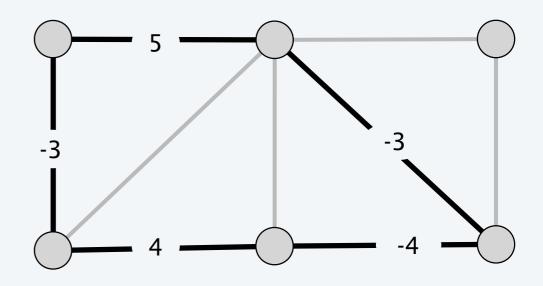

Shortest path problem. Given a digraph G = (V, E) with edge weights c_{vw} and no negative cycles, find cheapest $v \sim t$ path for each node v.

Negative cycle problem. Given a digraph G = (V, E) with edge weights c_{vw} , find a negative cycle (if one exists).

shortest-paths tree

negative cycle

Def. $OPT(i, v) = \text{cost of shortest } v \sim t \text{ path that uses } \leq i \text{ edges.}$

- Case 1: Cheapest $v \sim t$ path uses $\leq i 1$ edges.
 - OPT(i, v) = OPT(i 1, v)

- optimal substructure property (proof via exchange argument)
- Case 2: Cheapest $v \sim t$ path uses exactly i edges.
 - if (v, w) is first edge, then *OPT* uses (v, w), and then selects best $w \sim t$ path using ≤ i 1 edges

$$OPT(i,v) = \left\{ \begin{array}{l} \infty & \text{if } i=0 \\ \min \left\{ OPT(i-1, \ v) \,, \ \min_{(v,w) \in E} \left\{ \ OPT(i-1, \ w) + c_{vw} \ \right\} \right\} & \text{otherwise} \end{array} \right.$$

Observation. If no negative cycles, $OPT(n-1, v) = \text{cost of cheapest } v \sim t \text{ path.}$ Pf. By Lemma 2, cheapest $v \sim t$ path is simple. •

```
SHORTEST-PATHS (V, E, c, t)
FOREACH node v \in V
   M[0, v] \leftarrow \infty.
M[0, t] \leftarrow 0.
FOR i = 1 TO n - 1
   FOREACH node v \in V
      M[i, v] \leftarrow M[i-1, v].
      Foreach edge (v, w) \in E
         M[i, v] \leftarrow \min \{ M[i, v], M[i-1, w] + c_{vw} \}.
```

Theorem 1. Given a digraph G = (V, E) with no negative cycles, the dynamic programming algorithm computes the cost of the cheapest $v \sim t$ path for each node v in $\Theta(mn)$ time and $\Theta(n^2)$ space.

Pf.

- Table requires $\Theta(n^2)$ space.
- Each iteration *i* takes $\Theta(m)$ time since we examine each edge once. •

Finding the shortest paths.

- Approach 1: Maintain a successor(i, v) that points to next node on cheapest $v \sim t$ path using at most i edges.
- Approach 2: Compute optimal costs M[i, v] and consider only edges with $M[i, v] = M[i-1, w] + c_{vw}$.

Space optimization. Maintain two 1d arrays (instead of 2d array).

- $d(v) = \cos t$ of cheapest $v \sim t$ path that we have found so far.
- $successor(v) = next node on a v \sim t path.$

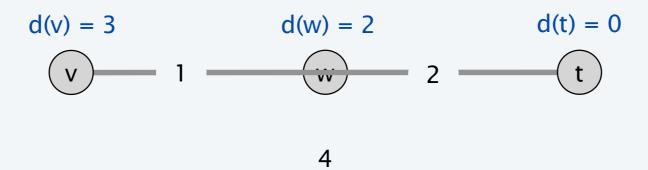

Performance optimization. If d(w) was not updated in iteration i-1, then no reason to consider edges entering w in iteration i.

```
BELLMAN-FORD (V, E, c, t)
FOREACH node v \in V
   d(v) \leftarrow \infty.
   successor(v) \leftarrow null.
d(t) \leftarrow 0.
FOR i = 1 TO n - 1
   FOREACH node w \in V
      IF (d(w)) was updated in previous iteration)
         Foreach edge (v, w) \in E
                                                           1 pass
             IF (d(v) > d(w) + c_{vw})
                d(v) \leftarrow d(w) + c_{vw}.
                successor(v) \leftarrow w.
   IF no d(w) value changed in iteration i, STOP.
```

Bellman-Ford: analysis

Claim. After the i^{th} pass of Bellman-Ford, d(v) equals the cost of the cheapest $v \sim t$ path using at most i edges.

Counterexample. Claim is false!

if nodes w considered before node v, then d(v) = 3 after 1 pass Lemma 3. Throughout Bellman-Ford algorithm, d(v) is the cost of some $v \sim t$ path; after the i^{th} pass, d(v) is no larger than the cost of the cheapest $v \sim t$ path using $\leq i$ edges.

Pf. [by induction on i]

- Assume true after i^{th} pass.
- Let *P* be any $v \sim t$ path with i + 1 edges.
- Let (v, w) be first edge on path and let P' be subpath from w to t.
- By inductive hypothesis, $d(w) \le c(P')$ since P' is a $w \sim t$ path with i edges.
- After considering v in pass i+1: $d(v) \le c_{vw} + d(w)$ $\le c_{vw} + c(P')$ = c(P)

Theorem 2. Given a digraph with no negative cycles, Bellman-Ford computes the costs of the cheapest $v \sim t$ paths in O(mn) time and $\Theta(n)$ extra space.

Pf. Lemmas 2 + 3.

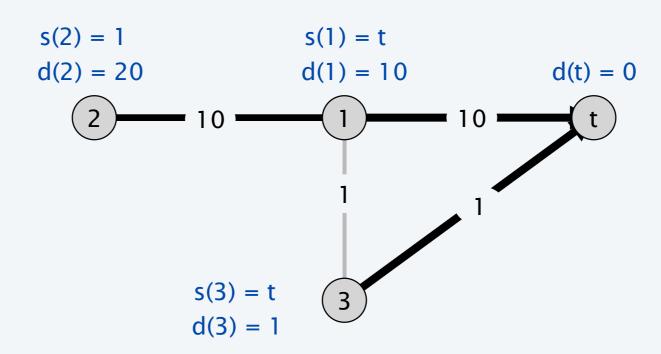

Bellman-Ford: analysis

Claim. Throughout the Bellman-Ford algorithm, following successor(v) pointers gives a directed path from v to t of cost d(v).

Counterexample. Claim is false!

• Cost of successor $v \sim t$ path may have strictly lower cost than d(v).

consider nodes in order: t, 1, 2, 3

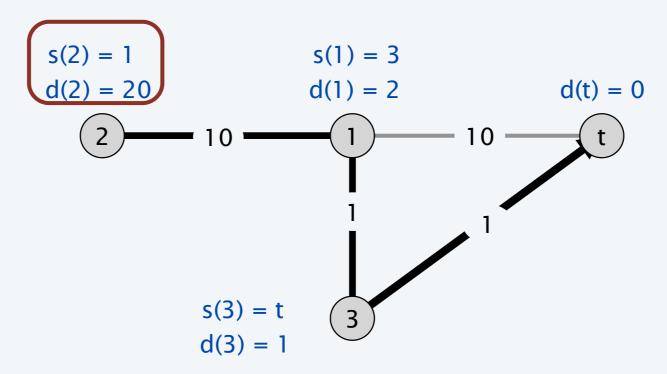

Bellman-Ford: analysis

Claim. Throughout the Bellman-Ford algorithm, following successor(v) pointers gives a directed path from v to t of cost d(v).

Counterexample. Claim is false!

• Cost of successor $v \sim t$ path may have strictly lower cost than d(v).

consider nodes in order: t, 1, 2, 3

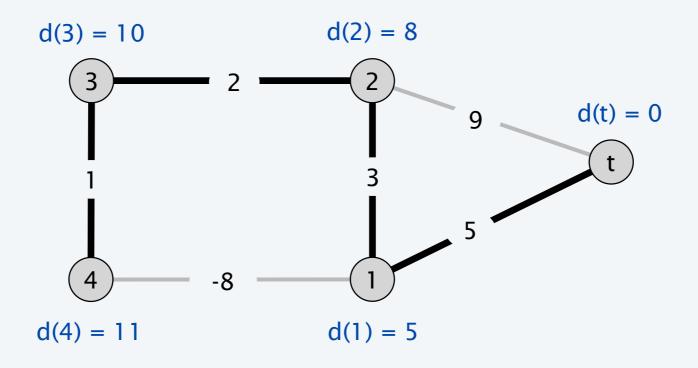

Bellman-Ford: analysis

Claim. Throughout the Bellman-Ford algorithm, following successor(v) pointers gives a directed path from v to t of cost d(v).

Counterexample. Claim is false!

- Cost of successor $v \sim t$ path may have strictly lower cost than d(v).
- Successor graph may have cycles.

consider nodes in order: t, 1, 2, 3, 4

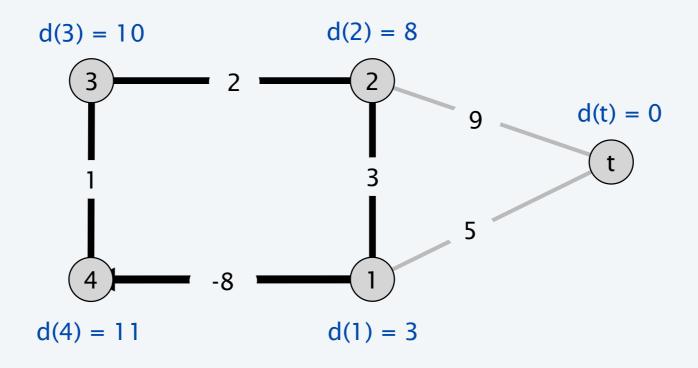

Bellman-Ford: analysis

Claim. Throughout the Bellman-Ford algorithm, following successor(v) pointers gives a directed path from v to t of cost d(v).

Counterexample. Claim is false!

- Cost of successor $v \sim t$ path may have strictly lower cost than d(v).
- Successor graph may have cycles.

consider nodes in order: t, 1, 2, 3, 4

Bellman-Ford: finding the shortest path

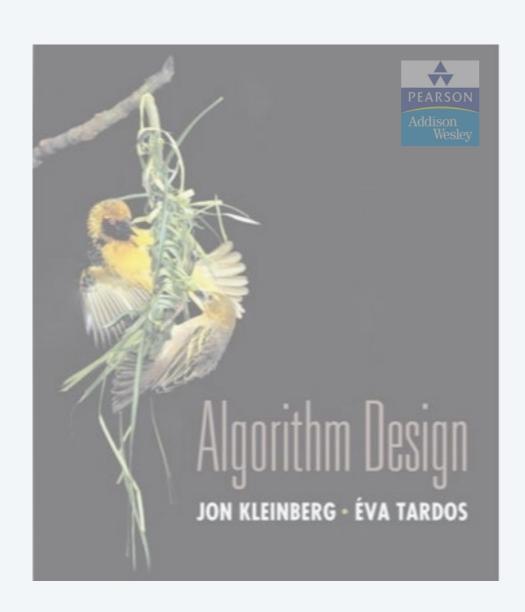

Lemma 4. If the successor graph contains a directed cycle W, then W is a negative cycle. Pf.

- If successor(v) = w, we must have $d(v) \ge d(w) + c_{vw}$. (LHS and RHS are equal when successor(v) is set; d(w) can only decrease; d(v) decreases only when successor(v) is reset)
- Let $v_1 \rightarrow v_2 \rightarrow ... \rightarrow v_k$ be the nodes along the cycle W.
- Assume that (v_k, v_1) is the last edge added to the successor graph.
- Just prior to that: $d(v_1) \geq d(v_2) + c(v_1, v_2)$ $d(v_2) \geq d(v_3) + c(v_2, v_3)$ $\vdots \qquad \vdots \qquad \vdots$ $d(v_{k-1}) \geq d(v_k) + c(v_{k-1}, v_k) \qquad \qquad \text{holds with strict inequality}$ $d(v_k) > d(v_1) + c(v_k, v_1) \qquad \qquad \text{since we are updating d(v_k)}$
- Adding inequalities yields $c(v_1, v_2) + c(v_2, v_3) + ... + c(v_{k-1}, v_k) + c(v_k, v_1) < 0$.

Theorem 3. Given a digraph with no negative cycles, Bellman-Ford finds the cheapest $s \sim t$ paths in O(mn) time and $\Theta(n)$ extra space.

Pf.

- The successor graph cannot have a negative cycle. [Lemma 4]
- Thus, following the successor pointers from s yields a directed path to t.
- Let $s = v_1 \rightarrow v_2 \rightarrow ... \rightarrow v_k = t$ be the nodes along this path P.
- Upon termination, if successor(v) = w, we must have $d(v) = d(w) + c_{vw}$. (LHS and RHS are equal when successor(v) is set; $d(\cdot)$ did not change)

6. DYNAMIC PROGRAMMING II

- sequence alignment
- Hirschberg's algorithm
- Bellman-Ford
- distance vector protocols
- negative cycles in a digraph

Communication network.

- Node \approx router.
- Edge \approx direct communication link.
- Cost of edge ≈ delay on link. ← naturally nonnegative, but Bellman-Ford used anyway!

Dijkstra's algorithm. Requires global information of network.

Bellman-Ford. Uses only local knowledge of neighboring nodes.

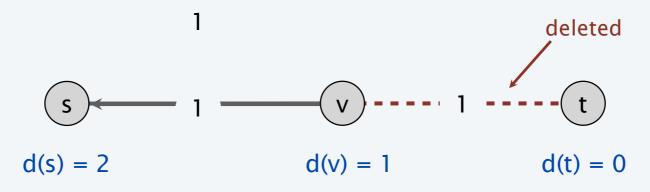

Synchronization. We don't expect routers to run in lockstep. The order in which each for each loop executes in not important. Moreover, algorithm still converges even if updates are asynchronous.

Distance vector protocols. ["routing by rumor"]

- Each router maintains a vector of shortest path lengths to every other node (distances) and the first hop on each path (directions).
- Algorithm: each router performs n separate computations, one for each potential destination node.

Ex. RIP, Xerox XNS RIP, Novell's IPX RIP, Cisco's IGRP, DEC's DNA Phase IV, AppleTalk's RTMP.

Caveat. Edge costs may change during algorithm (or fail completely).

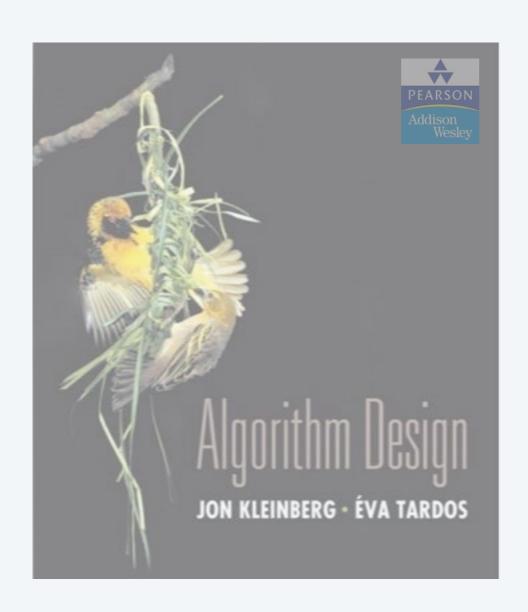

"counting to infinity"

Path vector protocols

Link state routing.

- not just the distance and first hop
- Each router also stores the entire path.
- Based on Dijkstra's algorithm.
- Avoids "counting-to-infinity" problem and related difficulties.
- Requires significantly more storage.

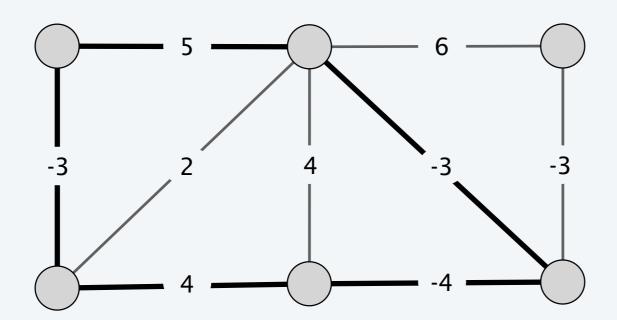

Ex. Border Gateway Protocol (BGP), Open Shortest Path First (OSPF).

6. DYNAMIC PROGRAMMING II

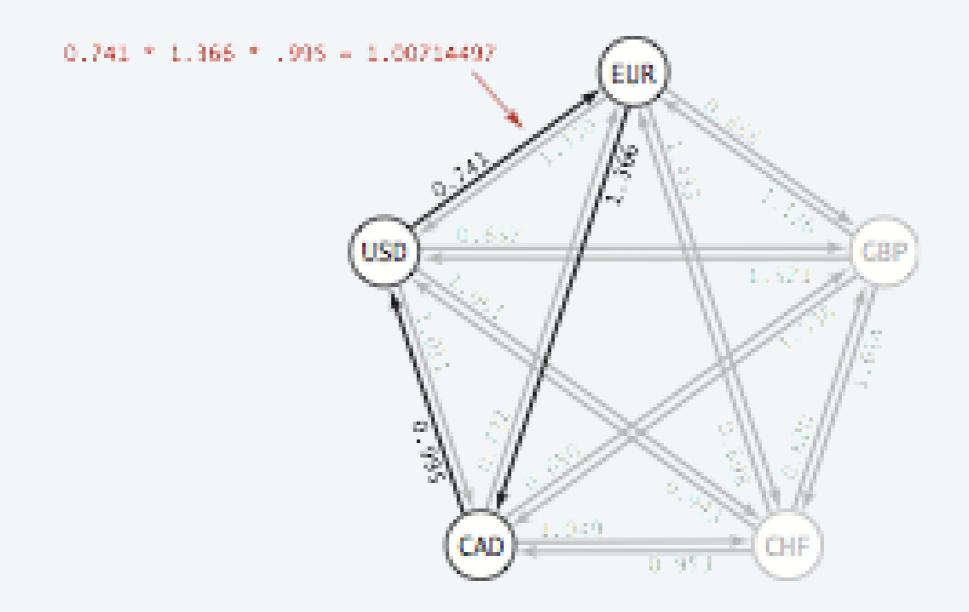

- sequence alignment
- Hirschberg's algorithm
- Bellman-Ford
- distance vector protocol
- negative cycles in a digraph

Negative cycle detection problem. Given a digraph G = (V, E), with edge weights c_{vw} , find a negative cycle (if one exists).

Currency conversion. Given *n* currencies and exchange rates between pairs of currencies, is there an arbitrage opportunity?

Remark. Fastest algorithm very valuable!

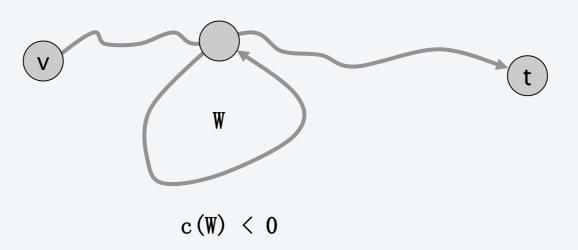

Lemma 5. If OPT(n, v) = OPT(n - 1, v) for all v, then no negative cycle can reach t.

Pf. Bellman-Ford algorithm. •

Lemma 6. If OPT(n, v) < OPT(n-1, v) for some node v, then (any) cheapest path from v to t contains a cycle W. Moreover W is a negative cycle.

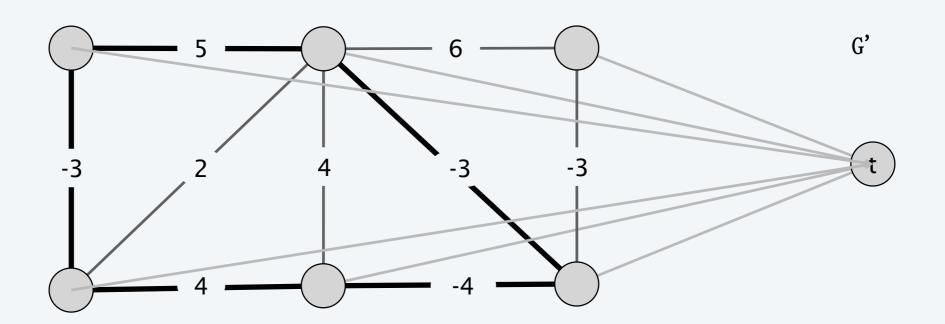

Pf. [by contradiction]

- Since OPT(n, v) < OPT(n-1, v), we know that shortest $v \sim t$ path P has exactly n edges.
- By pigeonhole principle, P must contain a directed cycle W.
- Deleting W yields a $v \sim t$ path with < n edges $\Rightarrow W$ has negative cost. •

Theorem 4. Can find a negative cycle in $\Theta(mn)$ time and $\Theta(n^2)$ space. Pf.

- Add new node t and connect all nodes to t with 0-cost edge.
- G has a negative cycle iff G' has a negative cycle than can reach t.
- If OPT(n, v) = OPT(n-1, v) for all nodes v, then no negative cycles.
- If not, then extract directed cycle from path from v to t.
 (cycle cannot contain t since no edges leave t)

Theorem 5. Can find a negative cycle in O(mn) time and O(n) extra space. Pf.

- Run Bellman-Ford for n passes (instead of n-1) on modified digraph.
- If no d(v) values updated in pass n, then no negative cycles.
- Otherwise, suppose d(s) updated in pass n.
- Define pass(v) = last pass in which <math>d(v) was updated.
- Observe pass(s) = n and $pass(successor(v)) \ge pass(v) 1$ for each v.
- Following successor pointers, we must eventually repeat a node.
- Lemma 4 ⇒ this cycle is a negative cycle. •

Remark. See p. 304 for improved version and early termination rule. (Tarjan's subtree disassembly trick)
